

AI Multi-Agent Sports Trade Analyzer — Design Document

1. Idea

Evaluating a pro-sports trade is really several smaller jobs done by different specialists: someone has to know the player data, someone has to judge whether the players are actually good value, and someone has to check the trade against the league's financial rules before it can even happen.

Instead of writing one large function that does all three, this project splits the work into four small, single-purpose "agents" that each do one job and hand their result to the next one — the same shape as a real NBA front office, and a common pattern in **agentic coding**: break a task into roles, give each role a narrow responsibility, and let them collaborate in sequence.

The project makes a second, deliberate point: **the math should never be left to an AI model**. Salary-cap rules and value scores are computed by plain, deterministic Python

(`notebooks/01_trade_analyzer_core.ipynb`) — auditable, testable, and always gives the same answer for the same input. An AI language model is only added afterward, as an optional layer (`notebooks/02_agentic_crew_demo.ipynb`), to turn already-verified numbers into a written recommendation. The AI adds explanation and judgment; it never invents a number.

2. Example

Input — a proposed trade:

```
{
  "team_a": "BOS",
  "team_b": "LAL",
  "team_a_sends": ["Jrue Holiday"],
  "team_b_sends": ["D'Angelo Russell", "Gabe Vincent"]
}
```

Output — the generated report:

Trade Analysis Report

Proposed trade: BOS sends Jrue Holiday to LAL for D'Angelo Russell, Gabe Vincent.

Boston Celtics (BOS) -- Grade: A

- Spending level: Under the Salary Cap (payroll \$151,250,500)
- Trade allowed: YES (outgoing \$32,400,000, incoming \$29,492,000, max allowed \$35,796,500)
- Value analysis: acquired 74.2, gave up 32.5, net +41.7
- Roster before trade: average age 30.4, positions {'SG': 1, 'PG': 2, 'C': 1, 'SF': 1}

Los Angeles Lakers (LAL) -- Grade: D

- Spending level: Under the Salary Cap (payroll \$113,919,000)
- Trade allowed: YES (outgoing \$29,492,000, incoming \$32,400,000, max allowed \$70,220,000)
- Value analysis: acquired 32.5, gave up 74.2, net -41.7
- Roster before trade: average age 28.8, positions {'PF': 2, 'PG': 2, 'SG': 1}

And a second example showing a trade the Cap Specialist rejects, with a suggested fix:

Boston Celtics (BOS) -- Grade: F (Not Allowed)

- Spending level: Over the Second Apron (payroll \$242,000,800)
- Trade allowed: NO (outgoing \$94,729,280, incoming \$18,692,000, max allowed \$94,729,280)
 - Problem: Teams at the strictest spending level cannot combine several outgoing players' salaries into one trade.
- Suggested fix: (none needed here -- the salary side was fine, only the "combining players" rule was broken)

Notebook 2 takes this same result and asks an AI model to turn it into a fuller written recommendation, without changing the grade or the numbers.

3. High-Level Architecture

The two notebooks sit on top of the same pipeline:

Notebook 2 never recomputes the numbers — it calls into notebook 1's already-verified functions through one tool, so the AI agents' final grades always match notebook 1's exactly.

4. Agent Roles

Agent	Responsibility	Reads	Produces	Implemented as
Data Scout	Load accurate roster, salary, and stat data for the teams involved	<code>data/sample_players.json</code> , <code>data/cap_rules.json</code>	Team rosters, per-player salary/age/stats	<code>find_player()</code> , <code>team_payroll()</code>
Analyst	Score each player's value, adjusted for age; summarize the trade's value trade-off	Player records	0–100 value score per player, net value score per team	<code>age_multiplier()</code> , <code>player_value_score()</code> , <code>analyze_team_needs()</code> , <code>trade_impact_summary()</code>
Cap Specialist	Check the trade against salary-cap/luxury-tax/apron rules; explain and suggest fixes for violations	Team payroll, outgoing/incoming salary, player count	Allowed/not-allowed verdict, list of problems, suggested fix	<code>team_cap_status()</code> , <code>check_trade_legality()</code> , <code>suggest_balancing_move()</code>
General Manager	Combine all of the above into one final graded report, no new calculation of its own	Outputs of the other three agents	Letter grade per team, full markdown report	<code>_grade()</code> , <code>run_trade_analysis()</code> , <code>render_markdown_report()</code>

In notebook 2, each of these becomes a `crewai.Agent` with a role, goal, and backstory, and a `crewai.Task` that runs in sequence, each one able to see the previous task's output (`context=[...]`). All four share one tool, `run_full_trade_analysis_tool` , which is the only bridge between the AI agents and the deterministic pipeline — the agents can read its result, but cannot bypass it to compute their own numbers.

5. Low-Level Design

Data model

```
data/sample_players.json
```

```
{
  "teams": {
    "BOS": {
      "name": "Boston Celtics",
      "roster": [
        {"name": "Jaylen Brown", "position": "SG", "age": 29,
          "salary": 49205800, "contract_years_remaining": 4,
          "per": 21.6, "win_shares": 8.4}
      ]
    }
  }
}
```

data/cap_rules.json

```
{
  "season": "2025-26",
  "salary_cap": 154647000,
  "luxury_tax_line": 187895000,
  "first_apron": 195945000,
  "second_apron": 207824000
}
```

Player value score

```
age_multiplier(age)  -> looked up from a fixed table, peaks at 1.00 around age 25-27
raw_score            = per * 2.2 + win_shares * 3.0
player_value_score   = min(raw_score * age_multiplier(age), 100), rounded to 1 decimal
```

trade_impact_summary(players_in, players_out) sums player_value_score across each list and returns value_acquired, value_surrendered, and net_value_score = value_acquired - value_surrendered.

Cap status and legality

```
team_cap_status(payload):
  payroll < salary_cap          -> UNDER_CAP
  payroll < luxury_tax_line     -> OVER_CAP_UNDER_TAX
  payroll < first_apron         -> TAXPAYER
  payroll < second_apron        -> FIRST_APRON
  else                         -> SECOND_APRON
```

Salary-matching limit by status:

Status	Max incoming salary allowed
Under the cap	<code>cap_room + outgoing_salary</code> , where <code>cap_room = salary_cap - payroll</code>
Over the cap / taxpayer	<code>outgoing ≤ \$7.5M → outgoing * 2.00 + \$250k ; ≤ \$29M → outgoing * 1.75 + \$250k ;</code> else → <code>outgoing * 1.25 + \$250k</code>
First apron	<code>outgoing_salary + \$250,000</code> , and outgoing player count must be 1
Second apron	<code>outgoing_salary</code> exactly, and outgoing player count must be 1

`check_trade_legality(...)` computes the applicable limit, compares it to the proposed incoming salary, and returns a `TradeLegalityResult` (a dataclass: `legal` , `cap_status` , `outgoing_salary` , `incoming_salary` , `max_incoming_allowed` , `violations: list[str]`).

`suggest_balancing_move(result)` — if illegal, computes `gap = incoming_salary - max_incoming_allowed` and returns a one-line suggestion naming the team and the dollar amount it needs to shed.

Grading

```
grade(net_value_score, legal):
    not legal      -> "F (Not Allowed)"
    net >= 15      -> "A"
    net >= 7       -> "B+"
    net >= 2       -> "B"
    net >= -2      -> "C+"
    net >= -7      -> "C"
    else          -> "D"
```

Pipeline entry point

```
run_trade_analysis(trade, teams, cap_rules) -> {
    "trade": trade,
    "teams": {
        team_a: {team_name, payroll_before, legality, balancing_suggestion,
                  needs_before, impact, grade},
        team_b: { ...same shape... },
    },
}
```

`render_markdown_report(result)` turns that dictionary into the markdown report shown in section 2.

Notebook 2's tool boundary

```
run_full_trade_analysis_tool(trade_json: str) -> str:
    trade = json.loads(trade_json)
    result = run_trade_analysis(trade)           # same function as notebook 1
    report = render_markdown_report(result)
    return json.dumps({"summary": {...}, "report": report})
```

This is the single point of contact between the AI agents and the deterministic engine — every agent task is given this same tool, so no agent can produce a grade or a dollar figure that didn't come from

`run_trade_analysis`.

File layout

```
data/
  cap_rules.json           # salary cap / tax / apron thresholds
  sample_players.json      # offline roster + salary + stat dataset
notebooks/
  01_trade_analyzer_core.ipynb  # Idea -> deterministic engine (sections 4-5 above, as code)
  02_agentic_crew_demo.ipynb    # AI agent layer on top, via CrewAI
.env.example / .env          # GEMINI_API_KEY / ANTHROPIC_API_KEY (see README)
